EDUCATION

Bachelor - Computer Science
Stockholm University
2013 - 2016

Courses studied
Royal Institute of Technology
2008-2009

High School
Westerlundska Gymnasium
2004 - 2007

SKILLS

- Product Management
- Full-stack Developer
- Service Design
- Customer Experience
- Servant Leader
- Agile

Olle Hällbom

PERSONAL PROFILE

As a Senior Developer, there are three things that I build my profession upon: **Customer experience**, **Developer Productivity** and **Stakeholder Management**.

When I join a new company, project, or product, the first thing I look for is at what level the team is excited about the customer and how to solve problems for them. For me, this is the most important point about whether the product and team will achieve great success. When I've understood that and decided whether this area needs any action or not, I want to know the other way around: what does the customer think and feel about the product? This is crucial because that should be the foundation of how the roadmap is built and how we design the user experience.

The second point is looking at the delivery process. Do we have a pipeline that allow us to solve problems for our users at a rate and with such a quality that both we and the customers are happy about? This would mean intersecting the full delivery pipeline. First, the soft parts are figuring out what the user needs and how we design a good user experience to solve their problems. To the programming parts of the process: do we have a robust foundation with a system architecture, coding principles, design system, quality assurance, etc. that allow us to ship features with ease?

The third part is to make sure that the team's roadmap aligns with the company's vision and goals. This is achieved by understanding, creating relationships, and aligning with our internal and external stakeholders.

Doing all of the above increases the probability of success for the company, team, and me personally.

WORK EXPERIENCE

Full-stack Developer
Accounts IQ - Dublin, Ireland

2024 -

Working in a fintech company in Ireland with an accounting software that has more than 20 years in the market. I'm working on the full stack, continuously building new features for the users and upgrading the system where needed. The main is built with ASP .Net web-forms which we continusly upgrade to an Vue frontend app and .NET Web APIs in the backend, together with a MS SQL server database.

Main technologies: ASP .NET , SQL, Vue.

Product Owner
Kaptena AB - Stockholm, Sweden

2023 - 2024

Working in a fintech startup with the role to take the digital products to the next level. To learn the product from the ground up, and to get into the dev team in the best way, I currently spend about 60-70% of my time coding (the whole stack). The rest of my time goes into structuring the product processes in the company. Over time the role will go into 100% product management. For now that means introducing a professional way of working with the backlog but mostly to make sure that what the dev team outputs is what our customers needs at the same time as creating a great user experience. There is a long way to go, and I'm currently getting together cross functional teams for different projects and introduces the Service Design process to make sure that what is presented for our customers is of the highest value for them.

6 months into this position I was selected to be part of the company's executive management team.

Main technologies: NestJS, Typescript, Mongoose, Vue3, Sentry, Heroku, Github.

Product Owner
Scania - Södertälje, Sweden

2020 - 2023

Product owner for Scania's sales tool to configure and quote the offering to Scania's customers. Gathering business needs from all Scania's global sales markets, converting these into visions and goals and setting a roadmap to achieve those together with the development teams.

Achievements: Reaching the global business targets for Scania's sales regions for 21/22, i.e. making sure the sales persons can in an efficient way sell all Scania offered services together with the vehicles. We made this happen by early on partnering up with key sales regions sales managers to understand their business needs and create a long term strategy on those insights. From that we created a rough long-term roadmap with high-level descriptions on what capabilities and functions the system needed to be able to do. Since I'm a strong believer in agile we needed to break that roadmap down into smaller parts that could be delivered standalone and would give good user value by themselves. The outcomes of those parts was decided by the whole development team together with inputs from the users of the system, Scania's salespersons. The long-term outcomes of these roadmaps was very well received by the sales regions.

Full-stack Developer
Scania - Sao Paulo, Brazil

2018 - 2020

Working as a full-stack developer and team lead for one of the teams in a multi-team project with developers based in Sweden, Brazil and India. Also has experience for a few months as scrum master for the team.

Achievements: As a project we completed two big projects during this time:

- Lifted a big monolithic application, backend and frontend, from local server hosting to AWS services.
- Converted the frontend app from AngularJS+DOJO to Angular 5+.

But my main personal achievement was something different. First, I was not really happy with the lift and shift strategy to go to AWS, since the project plan was for 6 months and it wouldn't give any real and direct user value, if anything we saw that it might even decrease the performance of the system in some areas. Of course it would be a good long term decision to leverage all the great services from AWS, but the application was created to live on internal servers and in my opinion would need a change in design before it could go to the cloud. And as most estimates the original one for this project came out wrong, and it took about 9 months to be able to run the application on AWS in production, and even worse the performance for the end users got much slower than we thought. At this point we couldn't do a rollback so we spent even more time making the situation stable after the go-live. As you probably understand this is not something I would call an achievement, even though we learned a ton during this time. So, what I'm really proud about my time here is that around the time before the big AWS project started I pushed my product owner to create some space for us to break out the most used and slow parts of the monolithic application into smaller services. The goal with this was twofold: first when the application was hosted on local servers there would be a big performance gain for the end users, and when that was achieved this part of the application would be much easier to transfer to AWS. It took a great amount of team work and upfront design, but in the end we ended up with two services where one was used on every user session and in some cases decreased page load from 20 to 2 seconds!

Main technologies: .NET Core, AWS (multiple services), Angular, Gitlab. Bash scripts.

Developer
Scania - Södertälje, Sweden

2016 - 2018

Worked mainly as a backend developer, even though exploring all aspects of the development cycle. Part of a project with five development teams working on the same codebase with multiple stakeholders so collaboration was a natural part of the daily work.

Achievements: Took on a project that no one really cared about: Automated Load and Performance testing. At the time performance testing on each rolled out increment was done manually by the L1/L2 support team in production after each release. The immediate issue was of course that this was very time consuming, but the second and maybe more important issue was the results were almost never acted on by the development teams. The user experience of the system regarding load time wasn't great. So it was about time for the dev teams to take lead in this area. At first I solved the issue with a tool already used in the organisation, Silk Performer, where the output of my work was test scripts that could be manually executed and the result data was presented in excel graphs, comparing to earlier release load test results. This was a good improvement from before, but it didn't tickle the nerve for developers to use often in the development process, or even before every release, so I needed to improve the automation of the execution. In parallel, the test team had been working on setting up a Selenium project to handle the test automation for the regression testing. So I transferred the logic from the Silk scripts to Selenium tests written in Java. After that I could setup the tests to be triggered on each release branch. There was a debate in the project whether the release pipeline should be blocked in case of poor performance, but I could convince the team that it should be blocked with the same performance thresholds used by the support team in the manual testing since those numbers were discovered by Business Analysts and Product Managers and agreed on with stakeholders and users of the system.

Main technologies: .NET Framework, C#, SQL, MongoDB, Java, Silk Performer, AngularJS, Javascript, HTML, CSS, Selenium, TeamCity, Powershell scripts, Scrum.
